Search for a Heavy SM Higgs Boson in the $H \to ZZ \to llqq$ Channel at ATLAS

Carl Gwilliam

UNIVERSITY OF LIVERPOOL

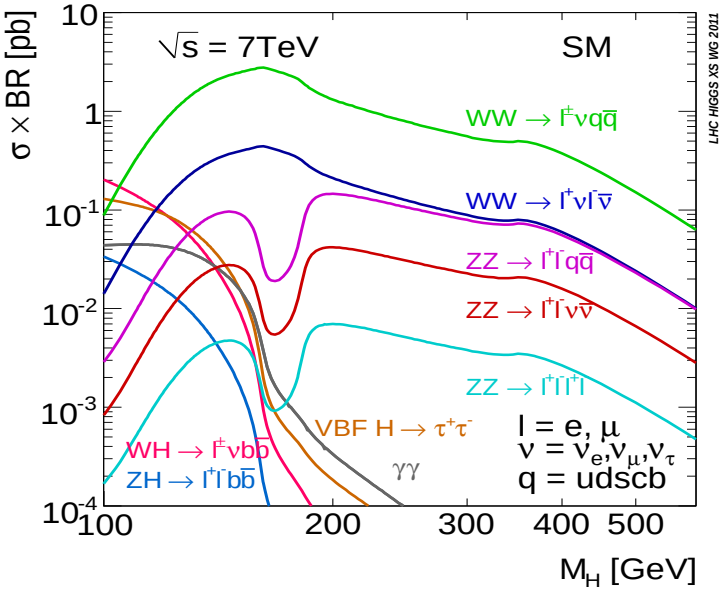
(on behalf of the ATLAS Collaboration)

29th July 2011

Higgs Hunting 2011, Orsay

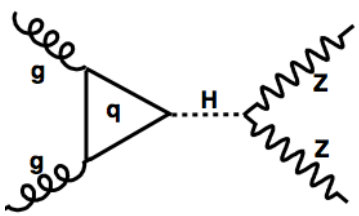
Introduction

- For a high mass Higgs ($m_H > 200$ GeV) ZZ and WW decay modes dominate
- "Golden" $H \to ZZ \to 4l$ is very clean but suffers from low branching fraction
- $H \to ZZ \to llqq$ has larger background but benefits from significantly higher BF

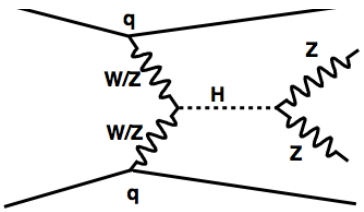


- Present the sensitivity of the ATLAS detector in this channel for 1.04 fb^{-1} at $\sqrt{s} = 7$ TeV in the range $200 \leq m_H \leq 600$ GeV

gluon fusion (dominant)



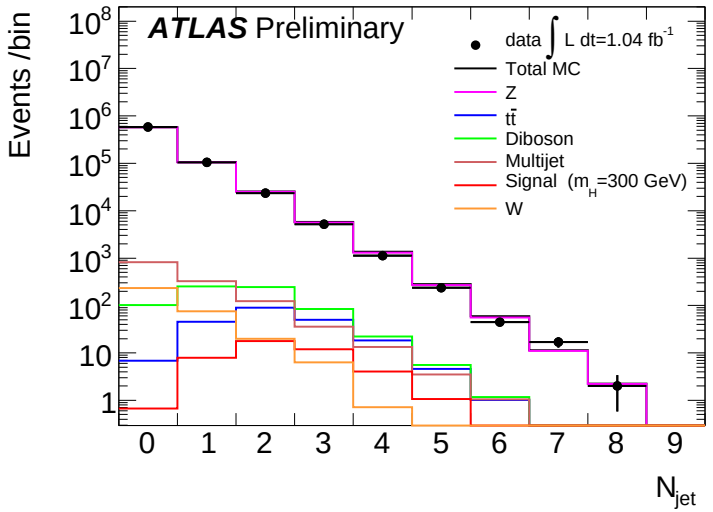
vector boson fusion (10-20%)

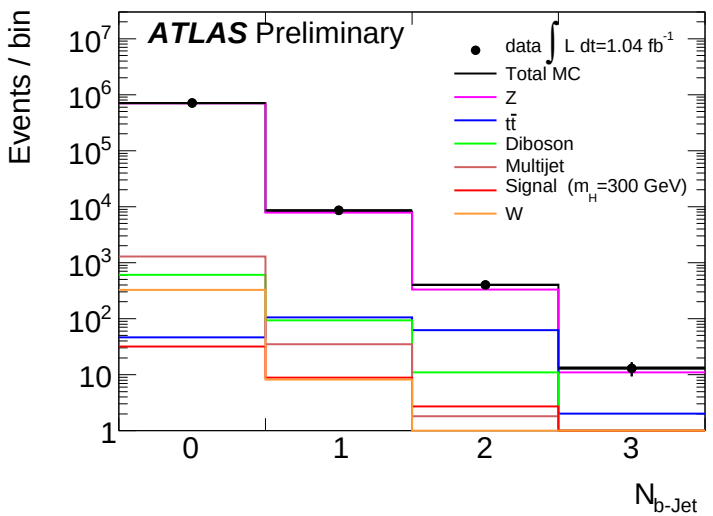


Signal modelled by NLO POWHEG MC generator interfaced to PYTHIA

Selection

- Leptonic Z candidate
  - 2 good isolated leptons (e/μ) with $p_T > 20$ GeV and $|\eta| < 2.5$
  - $76 < m_{ll} < 106$ GeV
- $E_T^{\text{miss}} < 50$ GeV
- Hadronic Z candidate
  - ≥ 2 jets with $p_T > 25$ GeV & $|\eta| < 2.5$
  - $70 < m_{jj} < 105$ GeV
- At high m_H the Z bosons from the H decay are boosted $\rightarrow$ Additional cuts:
  - $P_T^{\text{jet}} > 45$ GeV
  - $\Delta\phi_{ll} < 90°$ and $\Delta\phi_{jj} < 90°$



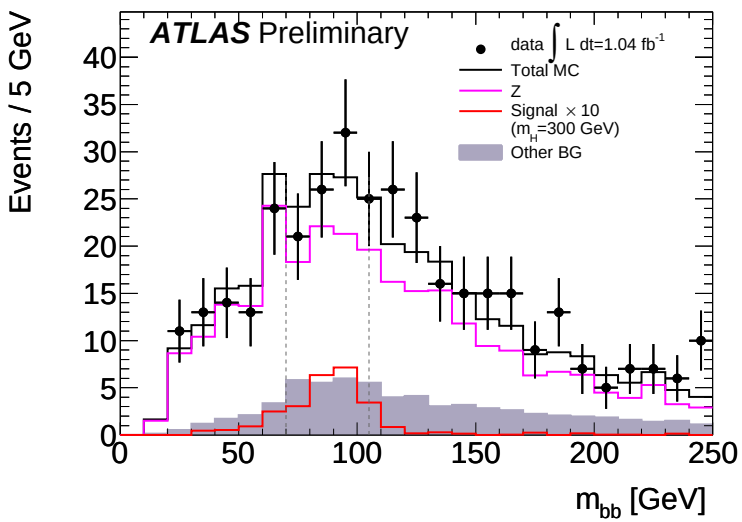


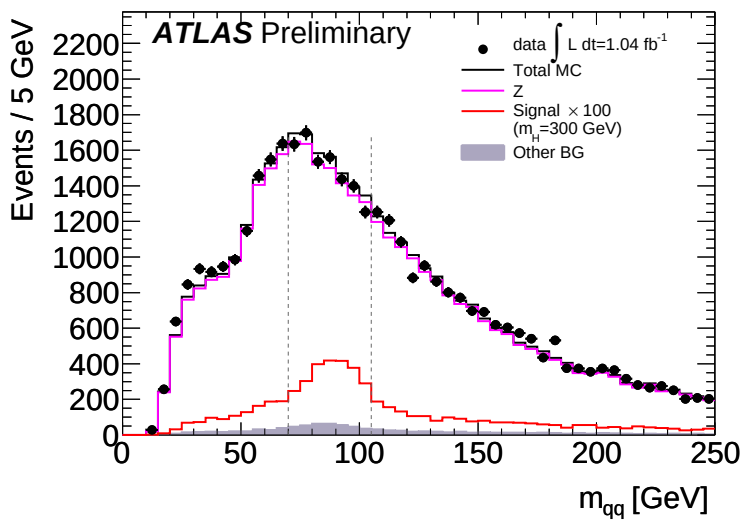
Selection (2)

- Split into two samples based on identification of jets from b decays
  - Based on a combination of secondary vertex reconstruction and impact parameter significance of tracks within jet to primary vertex $\rightarrow \epsilon_b \approx 70\%$

- "Tagged"
  - Events with exactly 2 b-jets
  - Form invariant mass from the 2 tagged jets

- "Untagged"
  - Events with < 2 b-jets
  - Form invariant mass from all combinations of 3 leading jets

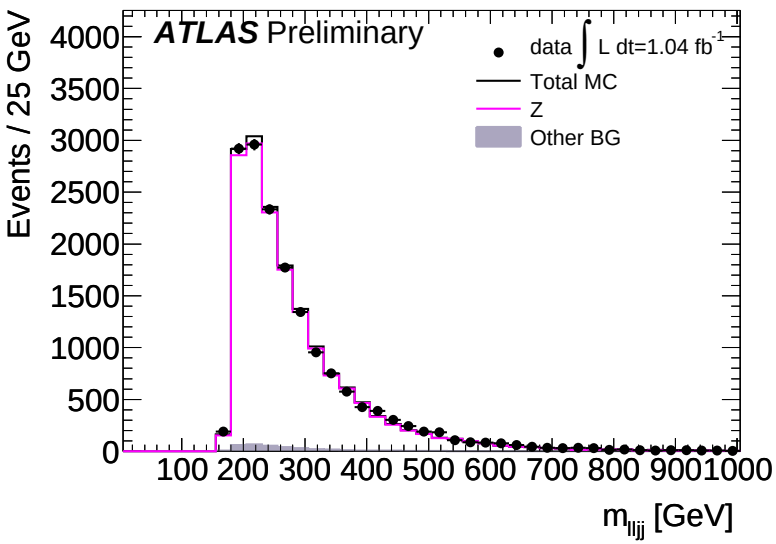




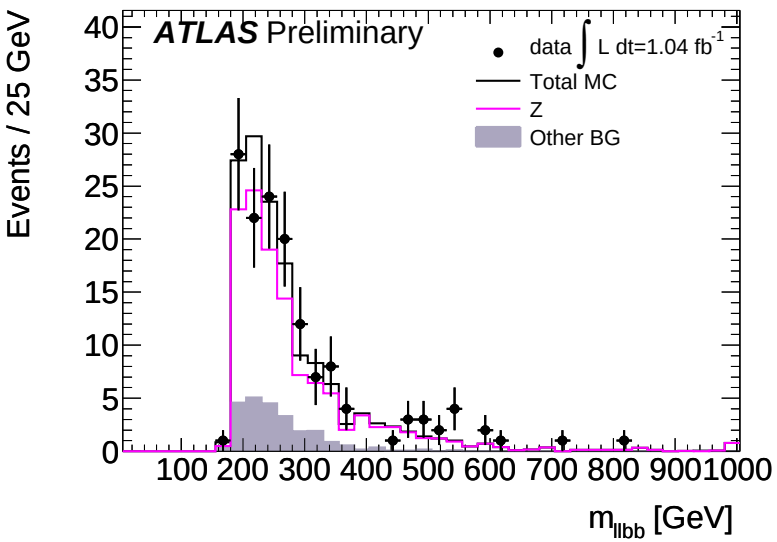
Z+jets Background

- Z+jets is the dominant background and is constrained using the m_{qq} sidebands
  - $40 < m_{qq} < 70$ GeV and $105 < m_{qq} < 150$ GeV
- Shape well described by ALPGEN but normalisation $\approx 10\%$ high
  - Consistent between tagged and untagged samples
- Use control region to determine scale factors to normalise MC

low m_H untagged



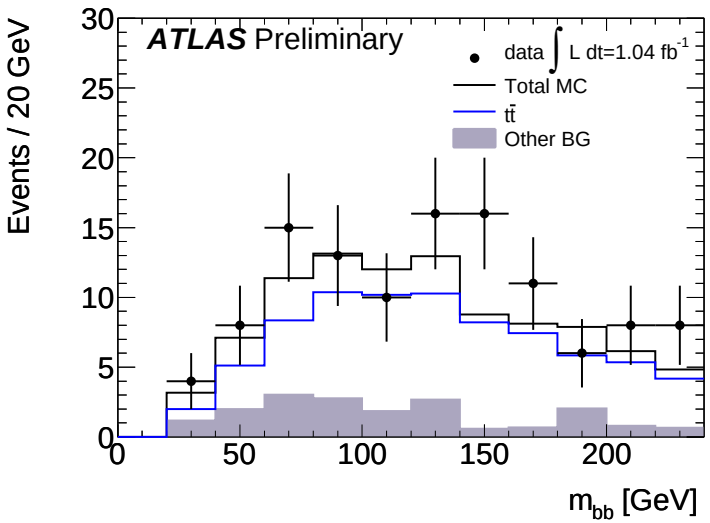
low m_H tagged



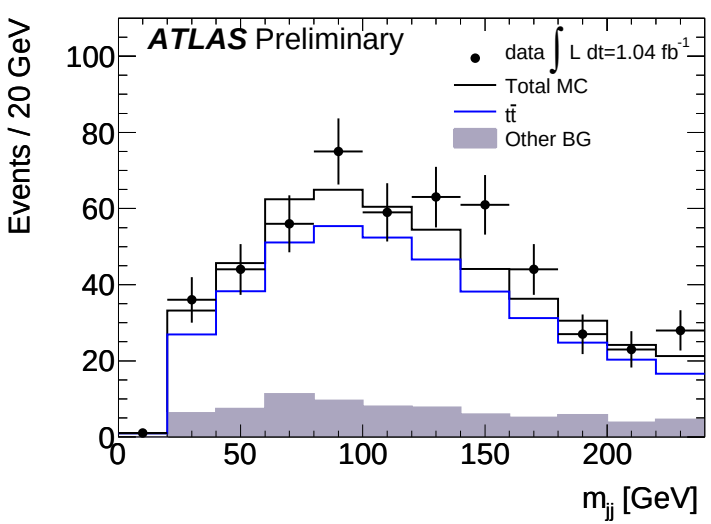
Top Background

- Top is an important background, particularly in the tagged sample
- Cross-checked using the sidebands of the m_{ll} distribution
  - $60 < m_{ll} < 76$ GeV and $106 < m_{ll} < 150$ GeV
  - For untagged sample also reverse E_T^{miss} cut
- Good description by MC@NLO Monte Carlo within errors

tagged, $E_T^{\text{miss}} < 50$ GeV



untagged, $E_T^{\text{miss}} > 50$ GeV

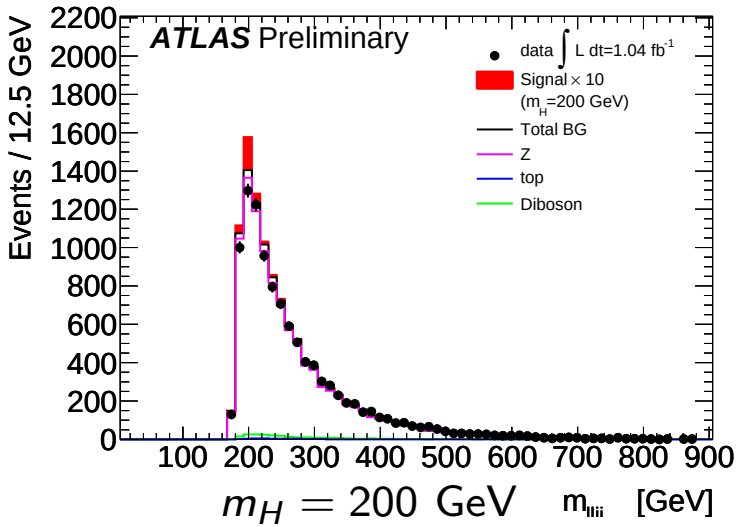


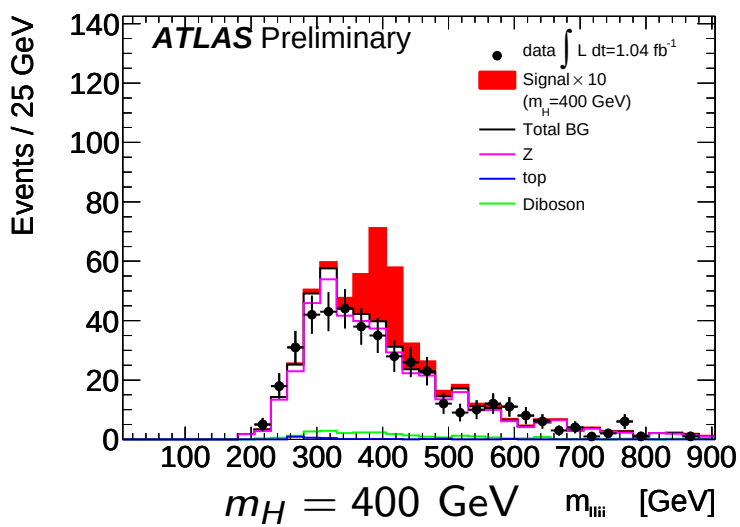
- Other backgrounds: QCD multijet production, also determined from data, and ZZ/WZ production, which are taken from MC@NLO

Results

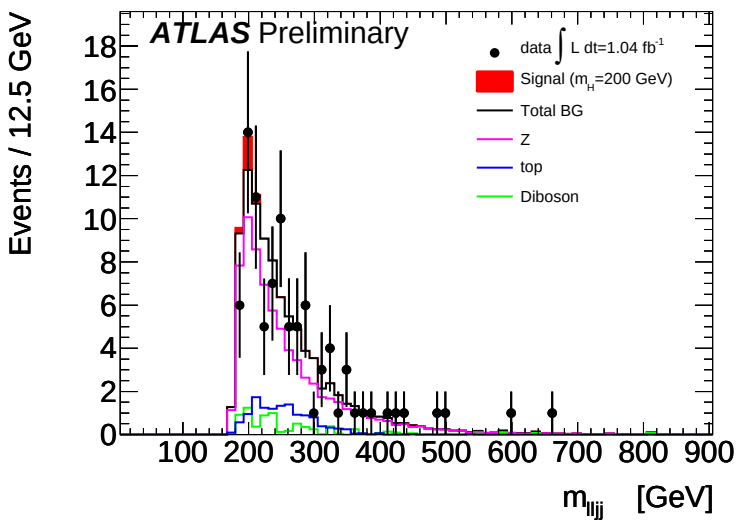
- No significant excess over SM background observed

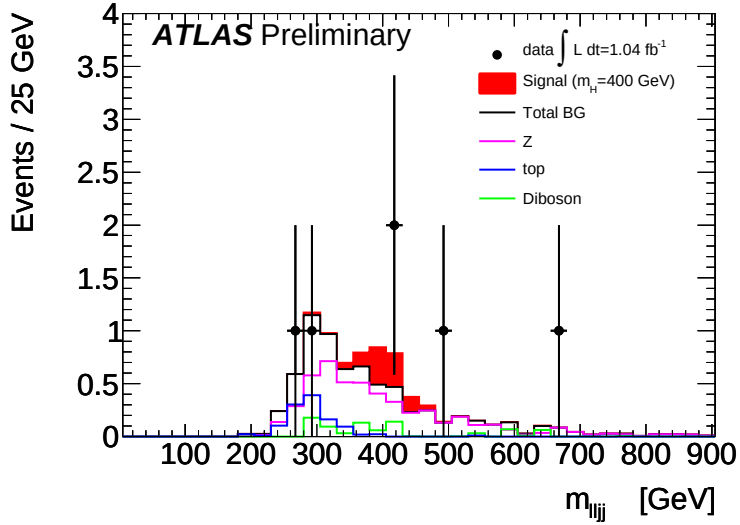
untagged





tagged



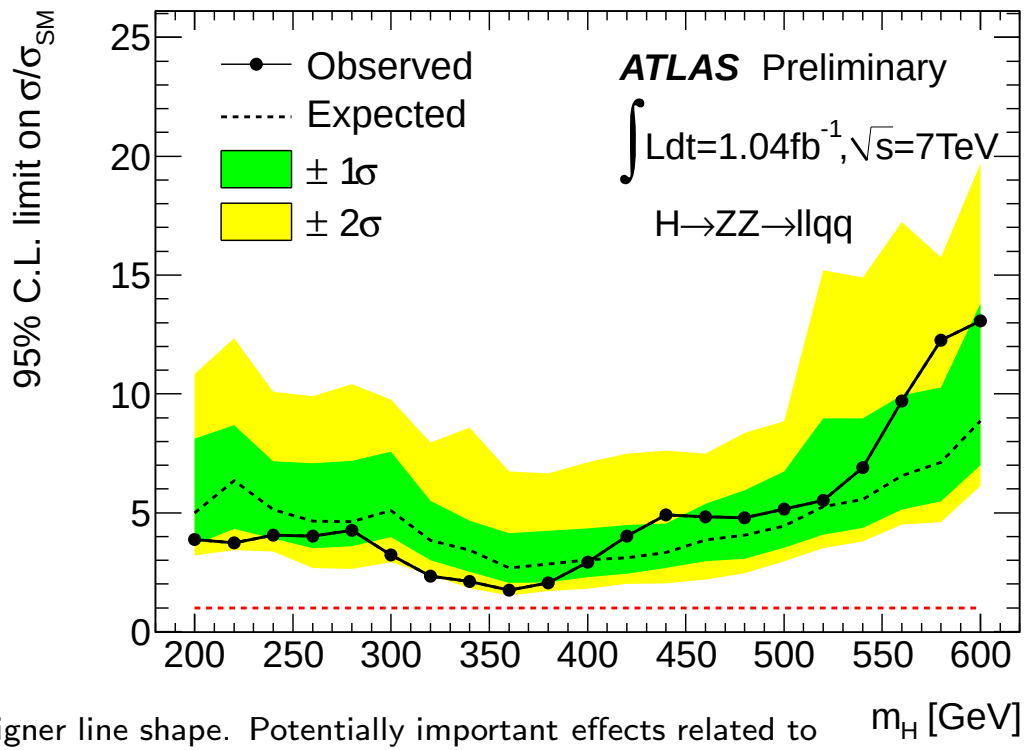


Systematic Uncertainties

- Signal
  - Cross section uncertainty: $15-20\%$ for $gg \to H$ & $3-9\%$ for $qq \to qqH$
  - Acceptance uncertainty by comparing POWHEG and PYTHIA
- Background normalisation
  - Z+jets uncertainty from comparing low and high m_{qq} sidebands $\to$ 1.4%/8.1% for low/high m_H untagged sample and 18% for tagged sample
  - 100% uncertainty for QCD multijet and 50% for W+jets
  - Theoretical uncertainty for top (9%) and ZZ/WZ (11%)
- Background shape
  - Z+jets: comparison between ALPGEN and PYTHIA
  - ZZ: comparison between MC@NLO and PYTHIA
- Luminosity: 3.7% (where normalisation not determined from data)
- Detector-related uncertainties on efficiency, E or p scale & resolution
  - Tagged: dominated by uncertainty on b-tagging efficiency (15-25%)
  - Untagged: Largest contribution is jet E scale (up to $\approx 5\%$) but jet E resolution, E_T^{miss} and b-tagging uncertainties also important

Exclusion Limits

- Combined exclusion limit on σ/σ_{SM} from tagged and untagged samples at 95% CL using *CLs* method
  - Use modified frequentist formalism with profile likelihood test statistic
  - The likelihood compares the full m_{lljj} distribution bin-by-bin to expected background or sum of expected signal and background
- Limit approaching σ_{SM} with $\int Ldt = 1.04\ \mathrm{fb}^{-1}$
- Exclude $1.7 \times \sigma_{SM}$ at $m_H = 360$ GeV
  - Correspnding expected limit is $2.7 \times \sigma_{SM}$
- Combined high mass $H \to ZZ/WW$ channels sensitive to σ_{SM}



† Limits based on on-shell Higgs with ad-hoc Breit-Wigner line shape. Potentially important effects related to off-shell Higgs boson production and interference eects are not included and may effect the limits for $m_H > 400$ GeV

Conclusion

- Have presented the sensitivity of the ATLAS detector in the $H \to ZZ \to 2l2q$ channel with 1.04 fb^{-1} at $\sqrt{s} = 7$ TeV
- No evidence for an excess above SM expectation observed
- Sensitivity ranges between 1.7 and 13 times SM cross section in the range $200 \leq M_H \leq 600$ GeV, with maximal sensitivity at 360 GeV
- Channel contributes significantly to the combined exclusion limit in the high mass range
- LHC and ATLAS are performing well so expect improved sensitivity very soon

Results Table

ATLAS Preliminary

The expected number of signal and background candidates for the Higgs boson search for 1.04 fb^{-1} in the $H \to ZZ \to \ell\ell qq$ channel, along with the observed numbers of candidates in data. Numbers with uncertainties are $\pm$ (stat.) $\pm$ (syst.), respectively, and the statistical component assumes Gaussian uncertainties.
