

SIMON FRASER UNIVERSITY ENGAGING THE WORLD

1

Tau Physics at ATLAS: recent results and prospects

Quentin Buat - Simon Fraser University

Séminaires du LAL - February 2nd, 2016

Run1 legacy: success of the Standard Model

- Discovery of the Higgs boson by ATLAS and CMS, driven by the bosonic final states
- Couplings and CP measurements confirm agreement with the SM expectations

Run1 legacy: beyond the Standard Model?

No new physics, lot of constraints on models at the TeV scale

Α	TLAS Exotics S	Search	es* -	95%	6 CL	Exclusion			ATLA	S Preliminary

*Only a selection of the available mass limits on new states or phenomena is shown.

Run2: 8 TeV \rightarrow 13 TeV

Increase of ~2 for 'common' processes, drives the trigger rates

Upgrading for two years

- New inner detector
 - Closest layer to the beam pipe.
- Trigger system upgrade
 - Increase L1 output rate from 75 to 100 kHz
 - New Central Trigger Processor
 - Merge L2 and HLT farms and additional ressources to increase output rate

Various other upgrade/consolidation

Insertable B Layer (IBL)

Back in business!

- Recorder 4.2fb⁻¹ of pp collisions, peak luminosity of 5.10³³ cm⁻² s⁻¹
- Very smooth operations, smaller dataset than expected

DAQ, Trigger

- DQ efficiency: 87%
 - main loss due to IBL off in 2 runs for safety reasons
- Luminosity: 3.2±0.2 fb⁻¹
 - Measured with vdM scans
- Very smooth trigger operations

Triggor	p _T Thresh	old (GeV)	Rate (Hz) *

 ΣE_{T} [GeV]

Tau Physics at the LHC

- The LHC is **<u>not</u>** a place to make precision measurements of the tau lepton
- As the heaviest lepton in the SM, the tau is a very useful probe of the EWSB mechanism:
 - Direct coupling the Higgs boson
 - Establishing the tau polarization in W/Z decays
 - Lepton Flavour Violation
- Many exotica and SUSY signatures involve taus, their discovery potential is usually weaker than signatures with light leptons (e/mu)

In this talk, instead of a broad review of the O(30) tau-related ATLAS results, I want to discuss the ATLAS strategy to <u>detect hadronically-decaying taus</u> and <u>highlight a few recent results</u>

Tau lepton at ATLAS

- $m_{\tau} = 1.777$ GeV, $c\tau = 87 \ \mu m$, decays: $\tau \rightarrow Iv$ (35%),
 - $\tau \rightarrow hadron(s) + v (65\%)$
- Leptonic tau decays are nearly indistinguishable from prompt light lepton
- Hadron collider vocabulary: <u>tau = hadronic decay</u> \approx <u>collection of π^{\pm} and π^{0} </u>

- Signature: calorimeter deposit associated with 1 or 3 tracks
- Reconstruction seeded by an anti-k_T jet algorithm with a radius of 0.4:
 - Core within 0.2, isolation ring [0.2, 0.4]
 - Tracks associated to the core or the isolation ring

Tau Energy Scale

- Seeded with an anti- k_T jet (dR=0.4) at the LC scale.
- MC-driven corrections to agree with the simulated true visible E_{T}
- Deconvolution method and in-situ Z→ττ measurement to provide a final ~1% correction and assert the systematic uncertainties:
 - ~2-3% for 1prong taus and 3-4% for 3prongs taus

Eur. Phys. J. C75 (2015) 303

Eur. Phys. J. C75 (2015) 303

Tau Identification

- Multivariate discriminant (BDT) based on a combinaison of calorimetric and track-based variables.
- Two discriminants trained separately for 1 prong and 3 prongs candidates
 - Very different calorimetric response, usage of displaced vertex possible in 3prongs
 - · Achieve an efficiency of 40% for a rejection of 60 (medium working point)

Tau Identification

- Very robust response agains pile-up obtained by explicitly correcting the input variables using $n_{\mbox{vtx}}$
- Agreement with data checked in $Z \rightarrow \tau \tau \rightarrow \mu \tau_h$ events
 - Scale factor deviates from unity by a few %

Eur. Phys. J. C75 (2015) 303

Triggering with taus?

- We try to avoid it but it is required for key signatures.
- Fully Hadronic final state: $BR(X \rightarrow \tau_h \tau_h) = 42\%$
 - Hadronic taus are the best trigger handle available
- Semi leptonic final state: $BR(X \rightarrow \tau_h \tau_l) = 46\%$
 - At low instantaneous luminosity, most searches can rely on the single lepton triggers
 - With the nominal Run2 setup, combined lepton + tau triggers will be required

ATLAS (Tau) Trigger System: Run1

Tau Trigger Run1 Performances

Efficiency wrt offline identified taus

ATLAS Trigger System: Run2 upgrade

- L1Topo: 128 items available for combination
- L1Calo:

Relative isolation cut

- L2/EF merger:
 - Topo-clustering available right at the L1 output.
 - Full tracking limited to the RoI
 - usually not fast enough to be run right at the L1 output (need a L2-like preselection)
- FTK:
 - Full scan of the tracking system right at the L1 output. Available in 2016...

Tau Trigger Run2 Performances

- Better performances than Run1
 - Relative Isolation at the L1
 - Cell-level precision available at the L1 output rate (EF/L2 merged)
 - HLT/offline ID menu harmonized

Tau Trigger Run2: Efficiency Measurement

- Tag&Probe analysis using $Z \rightarrow \tau \tau \rightarrow \mu \tau_h$ events: very good agreement with simulation
- Data/simulation scale-factors measured close to unity.

Tau Particle Flow

- Identify and classify the different hadronic decay modes:
 - Crucial information for decaydependent measurements
 - Improve the energy resolution

- **1.** Reconstruct and identify individual neutral pions within the tau energy deposit:
 - Estimate EM energy from charged pions using E_{trk} - E_{HAD} . Combine EM shower shape variables into a BDT do discriminate π_0 from pile-up and h± remnants cluster.
- 2. Using the first layer of the ECAL, attempt to disentangle cases where two neutral pions share the same cluster.
- 3. Combine with the charged information from the tracking system to classify the tau and measure its kinematic properties

Tau Particle Flow: Classification

- Efficient separation of decays with and without neutral pions
- A lot of 1p2n to 1p1n migration

Tau Particle Flow: Energy Resolution

- Decay classification allows a more reliable use of the tracking information to measure pT
- Huge gain in the core of the distribution
- Poor resolution in misclassified decays, need to combine with calo-only (run1 approach) method

Tau detection at ATLAS

- Run1 tau reconstruction was very successful and used for key ATLAS analysis
- Tau Energy Scale is measured within a few %
- Tau Identification algorithms have a good efficiency of (60% for the medium WP) with a powerful jet suppression allowing for tau final states to be detected
- Run2 tau reconstruction:
 - Successful commissioning (both offline and trigger)
 - Target to validate and use the new Tau Particle Flow strategy in 2016

Higgs coupling to fermions: $H \rightarrow \tau \tau$

- Large branching ratio
- Presence of leptons in the Final States (less background than H→bb)
- Only leptonic decay reachable by the LHC (H→µµ should be visible in HL-LHC)
- All the production modes reachable by the LHC

Does the 125 GeV boson decay to τ -lepton pairs ?

- Event categorized to target VBF and ggH production modes separately, all tau-decays considered
- MVA analysis to exploit most of the kinematic properties:
 - Boosted Decision Trees trained to separate the background from $H(125) \rightarrow \tau \tau$
 - Particularly powerful in the VBF category

τ-embedded data

- Z(→II)+jets measurements: large data/MC modelling
 - Require a sophisticated reweighing to model $Z(\rightarrow \tau \tau)$ +jets
- Using τ -embedded Z($\rightarrow \mu \mu$)+jets data:
 - very good modelling

- Run1 H \rightarrow tt heavily relies on MVA techniques
 - Improves the sensitivity from 2.5σ (cut-based) to 3.5σ
 - BDT trained to separate H(125) from the background, but also MissingMassCalculator, offline (and online!) BDT for tau ID, ...
- Higgs ML challenge
- New techniques could be investigated:
 - Deep Neural Networks are becoming more and more popular (winner of the Higgs ML challenge).
 - Potential applications in ATLAS: energy calibration, particle ID, jet substructure, sig/bkg separation...
 - Matrix Element techniques: expensive computing needs are becoming reachable with GPU clusters

Run 1 Analysis: results

 $\mu = 1.42^{+0.27}_{-0.26} \text{ (stat.)} {}^{+0.33}_{-0.25} \text{ (syst.)} \pm 0.1 \text{ (theory syst.)}$

- Observed (expected) significance: 4.5 (3.5) σ
- Measured signal strength consistent with the SM in all channels/categories

ATLAS+CMS Higgs combination

- Combining with CMS, claim discovery (>5 σ) of the tau coupling to the 125 GeV Higgs
- $H \rightarrow \tau \tau$ brings strong constraints on k_F
- Similar constraint to $H \rightarrow WW$ to the VBF production mode.

H→ττ prospectives: Run2 and beyond

- Extension of the SM:
 - high mass search in the $\tau\tau$ final states
 - Lepton Flavour Violation
- Test the SM with <u>new</u> and <u>more precise</u> Higgs property measurements
 - Observation of the VH production mode
 - Inclusive and differential cross-section
 - Hff CP quantum numbers
 - HVV and ggH couplings in VBF
- Higgs self-coupling

H→ττ prospectives: Run2 and beyond

- Extension of the SM:
 - high mass search in the $\tau\tau$ final states
 - Lepton Flavour Violation
- Test the SM with <u>new</u> and <u>more precise</u> Higgs property measurements
 - Observation of the VH production mode
 - Inclusive and differential cross-section
 - Hff CP quantum numbers
 - HVV and ggH couplings in VBF
- Higgs self-coupling

Search for High Mass Neutral Higgs

- First ATLAS run2 results with taus
- Many extensions of the SM predict • an extended Higgs sector
- MSSM favours down-type fermion • couplings at high tan β
- ggH and associated-b productions are considered in this search

Search for High Mass Neutral Higgs

- Search performed in the hadronic channels
- Fake background estimated using datadriven techniques
- Z+jets, top and diboson from simulation

Search for High Mass Neutral Higgs

- In MSSM m_h^{mod+} , the strongest constraint is tan β >10 for m_A = 200 GeV
- For $m_A > 700$ GeV, the run1 result is superseded.

Lepton Flavour Violation: $H \rightarrow \tau \mu$

- LFV couplings can occur in many SM extensions
- BR(H \rightarrow eµ) < O(10⁻⁸): strong constraints from µ \rightarrow eγ searches
- BR(H \rightarrow $\tau\mu$) < O(10%): loosely constrained from $\tau \rightarrow \mu\gamma$ searches
- CMS H→τµ search has a slight excess of 2.4σ. They exclude BR(H→τµ) < 1.57% at 95% CL

Lepton Flavour Violation: $H \rightarrow \tau \mu$

- Analysis performed in the $\tau_h\mu$ final state
- Background estimation similar to the H→ττ analysis, dedicated tune of the mass estimator
- Slight excess corresponding to 1.3σ
- BR(H→τµ) < 1.85% at 95% CL.
 Weaker than CMS limit but no combination (yet) with the eµ channel.

$H \rightarrow \tau \tau$ prospectives: Run2 and beyond

- Extension of the SM:
 - high mass search in the $\tau\tau$ final states
 - Lepton Flavour Violation
- Test the SM with <u>new</u> and <u>more precise</u> Higgs property measurements
 - Observation of the VH production mode
 - Inclusive and differential cross-section
 - Hff CP quantum numbers
 - HVV and ggH couplings in VBF
- Higgs self-coupling

Higgs properties: VH→ττ

- Search carried in hadronic channels $VH \rightarrow \tau\tau$, still completely stat-dominated
- WH $\rightarrow \tau_h \tau_l$ is the most sensitive channel (also the least affected by Fakes)
- Run2 dataset should provide observation/exclusion of VH→ττ at the SM expected rate

Higgs properties: incl. and diff. cross-sections

- Get the 5σ (inclusively and per production mode)!
- Strong VBF signal in H→ττ
 - Good place to measure fiducial corrections that still have large O(6-10%) systematic uncertainties
- Probe High pT regime of the Higgs boson

 H+jets: Break degeneracy with a high-pt jet that resolves the top loop but not the NP-loop

Higgs properties: HVV vertex

- Probe HVV tensor structure by exploiting large VBF signal
- Run1 analysis in preparation:
 - Cut on the BDT score to select high VBF Higgs purity events

Proof of principle, analysis to be repeated with Run2 data

Higgs properties: Hff vertex

- Test CP of the Yukawa Hff coupling
- Access through spin correlation and angular distribution of tau decay products
- New Tau Particle flow will bring:
 - Mode-specific angle calculation. For example exploit the τ→ρ decay mode

Phys. Rev. D 92, 092004 (2015)

DiHiggs: HH→bbττ

- Sensitivity to the SM not expected before HL-LHC dataset
- DiHiggs search carried in bbWW, bbγγ, bbττ and bbbb final states
- Still room for a lot of improvements with HL-LHC upgrade
 - 1MHz L0, L1 tracking
 - High eta coverage

Analysis	$\gamma\gamma bb$	$\gamma\gamma WW^*$	bb au au	bbbb	Combined
	Upper limi	t on the cross s	ection relativ	re to the S	M prediction
Expected	100	680	130	63	48
Observed	220	1150	160	63	70

Things that go bump in the light*

- Deviation from the SM expectations observed around 750 GeV in the diphoton spectrum
- Using a narrow width resonance, the local p_0 is estimated at 3.6 σ (2.0 σ global)
- Width ~ 45 GeV
- Can we see it in the ditau final state?

Conclusion

- LHC Run1 program was very successful for tau physics
 - Observation of Higgs coupling to the tau lepton by ATLAS and CMS
- Successful energy upgrade of the LHC in 2015
 - Commissioning the tau trigger, validating the offline/online algorithms
 - Preliminary results supersede the Run1 limits on the MSSM Higgs at high $\mbox{tan}\beta$
- The 2016 dataset will allow for more precise measurements in $H \rightarrow \tau \tau$
 - Stay tuned!

Additional Material

Tau Energy Scale Uncertainties

- Tau Energy Scale uncertainties are calculated using the deconvolution method
- Uncertainties on particle energies taken from E/p measurements in low mu runs, test beam studies and simulation are propagated to the constituents of hadronic tau decays

Source	Uncertainty [%]
Response	1.2 - 2.5
Detector model	0.3 - 2.5
UE	0.2 - 2.4
Pile-up	0.5 - 2.0
Non-closure	0.5 - 1.2
Shower model	0.0 - 2.0
Total	1.8 - 3.9
