## Application of WaveCatcher/SAMPIC digitizers for the readout of a plastic scintillator based ToF detector

*mercredi 7 février 2018 15:10 (25 minutes)*

Plastic scintillator detectors have been extensively used in particle physics experiments for decades. In large-scale experiments, they are typically arranged as an array of staggered long bars covering a large surface and provide a fast trigger signal or particle identification. This technology is proposed for the timing detector of the SHiP experiment at CERN SPS. Results of test-beams are presented.

In this study the scintillating light was read out at both ends of a long scintillator bar by photosensors (either photomultiplier tubes or array of large-area SiPMs) whose pulse shapes were recorded by waveform digitizers.

Results obtained with the WaveCatcher and SAMPIC digitizers are analyzed and compared. A discussion of the various factors affecting the timing resolution the bar is presented.
